Cognitive Neuroscience Seminar

Why label brains?

Labels visually augment anatomy

- teach brain anatomy
- guide neurosurgery

Why label brains?

Labels visually augment anatomy

- teach brain anatomy
- guide neurosurgery

Labels compartmentalize image data

- assign results to brain regions
- quantify data by brain region

Why label brains?

Labels visually augment anatomy

- teach brain anatomy
- guide neurosurgery

Labels compartmentalize image data

- assign results to brain regions
- quantify data by brain region

Labels provide a common nomenclature

- compare individuals within and across studies
- communicate results with a common language

How should we label brains?

Represent nested features within a graph-based data model

Top: structures: surface patches fragmented by application of the Laplace-Beltrami operator, sulcus folds and subfolds, and structures within a subfold.

Bottom: schematic diagrams representing the hierarchical relationships among nested structures.

Bottom right: features as properties of edges (relationships: Part of, Connected to, Has label) and nodes (geometric, shape, spectral, and connectivity measures).

Mindboggle 2: feature-based labeling

atlas

target

Mindboggle 2: feature-based labeling

Step 1: extract structures, compute their features

Mindboggle 2: feature-based labeling

Step 2: match atlas and target features

Mindboggle 2: feature-based labeling

Step 3: register atlas and target structures

Mindboggle 2: feature-based labeling

Step 2: or match features...

Mindboggle 2: feature-based labeling

Step 3: then propagate labels within inferred label boundaries

Mindboggle 2: feature extraction feature matching feature-based labeling

Combine structures across modalities

A gray/white matter surface (left lateral view) with visible sulcal pits highlighted (cyan circles). These features go by different names (sulcal roots, buried or annectant gyrii, plis de passage) and may be well conserved structures formed early in development.

DTI connectivity graph (same subject). Vertices represent all extracted sulcal pits and each edge width indicates a connection probability greater than 0.01 between two vertices (and does not follow a tractography path).

Match “brain graphs”

Early attempt at subgraph extraction (upper row) and matching (lower row).
These graphs were constructed from (left to right) a remitter, non-remitter, and control subject.
The subgraphs in red in the lower row have the highest small-worldness ratio.

Characterize anatomical variability

Example of natural morphological variability: left inferior parietal lobule (IPL; Kiriyaama et al. 2009).

(A-D) are MRI data and (E-G) are post-mortem specimens.

(A) IPL is highlighted and folds are outlined.

(B,E) Typical folding pattern.

(C,F) PreSMG pattern: an additional gyrus (ellipse) lies between postCS and SMG.

(D,G) PreAG pattern: an additional gyrus (ellipse) lies between SMG and AG.

[SMG: supramarginal gyrus; AG: angular gyrus; postCS: postcentral sulcus; IPS: intraparietal sulcus; Sy: Sylvian fissure, STS: superior temporal sulcus; *sulcus intermedius primus]
